

# Software Engineering (303105253)

## Unit – 2: Software Project Management

---

**Dr. Rachit Adhvaryu,**  
Assistant Professor, Computer Science & Engineering

## Outline

- W<sup>5</sup> of Project Management
- Software Metrics
  - Process, Product and Project Metrics
- Software Project Estimations
- Software Project Planning (MS Project Tool)
- Project Scheduling and Tracking
- Risk Analysis and Management
  - Risk Identification
  - Risk Projection
  - Risk Refinement
  - Risk Mitigation

# Software Project Management

## W<sup>5</sup>HH of Project Management

**Boehm** suggests **an approach (W<sup>5</sup>HH)** that addresses **project objectives, milestones and schedules, responsibilities, management and technical approaches, and required resources**

### **Why** is the system being developed?

Enables all parties to assess the validity of business reasons for the software work. In another words - does the business purpose justify the expenditure of people, time, and money?

### **What** will be done?

The **answers to these questions** help the team to **establish a project schedule** by **identifying key project tasks** and the **milestones** that are required by the customer

### **When** will it be accomplished?

Project schedule to achieve milestone

# W<sup>5</sup>HH of Project Management Cont.

## **Who** is responsible?

Role and responsibility of each member

---

## **Where** are they organizationally located?

Customer, end user and other stakeholders also have responsibility

---

## **How will** the job be done technically and managerially?

Management and technical strategy must be defined

---

## **How much** of each resource is needed?

Develop estimation

**W<sup>5</sup>HH**

It is applicable **regardless** of **size** or **complexity** of software **project**

# Terminologies

## ► Measure

- It provides a **quantitative indication** of the extent (**range**), **amount**, **dimension**, **capacity** or **size** of some attributes of a product or process
- Ex., the number of uncovered errors

## ► Metrics

- It is a **quantitative measure** of the degree (**limit**) **to which** a **system**, component or process possesses (obtain) a given attribute
- It **relates individual measures** in some way
- Ex., number of errors found per review

## ► Direct Metrics

- **Immediately measurable attributes**
- Ex., Line of Code (LOC), Execution Speed, Defects Reported

## ► Indirect Metrics

- **Aspects that are not immediately quantifiable**
- Ex., Functionality, Quantity, Reliability

## ► Indicators

- It is a **metric or combination of metrics** that provides **insight into the software process**, project or the product itself
- It **enables** the **project manager** or software engineers **to adjust** the process, the project or the product **to make things better**
- Ex., Product Size (analysis and specification metrics) is an indicator of increased coding, integration and testing effort

## ► Faults

- **Errors** - Faults found by the practitioners during software development
- **Defects** - Faults found by the customers after release

# Why Measure Software?

- 1 To **determine** (to define) **quality** of a product or process.
- 2 To **predict qualities** of a product or process.
- 3 To **improve quality** of a product or process.

## Metric Classification Base

### ► Process

- Specifies **activities related to production** of software.
- Specifies the abstract set of activities that should be performed to go from user needs to final product.

### ► Project

- **Software development work** in which a software process is used
- The actual act of executing the activities for some specific user needs

### ► Product

- **The outcomes of** a software **project**
- All the outputs that are produced while the activities are being executed

# Process Metrics

- ▶ Process Metrics are an invaluable **tool** for companies to monitor, **evaluate** and **improve** their **operational performance** across the enterprise
- ▶ They are **used** for making **strategic decisions**
- ▶ Process **Metrics** are **collected across all projects** and over **long periods of time**
- ▶ Their **intent** is to **provide a set of process indicators** that lead to long-term software **process improvement**

Ex., **Defect Removal Efficiency (DRE)** metric  
*Relationship between **errors (E)** and **defects (D)***

The **ideal** is a **DRE** of 1

$$\text{DRE} = E / (E + D)$$

We measure the effectiveness of a process by deriving a set of metrics based on outcomes of the process such as,

**Errors uncovered** before release of the software

**Defects delivered** to and reported by the end users

**Work products** delivered

**Human effort** expended

**Calendar time** expended

**Conformance** to the **schedule**

**Time and effort** to **complete** each generic **activity**

# Project Metrics

- ▶ Project **metrics enable** a software project **manager** to,
  - ↳ **Assess the status** of an ongoing project
  - ↳ **Track** potential **risks**
  - ↳ **Uncover problem areas** before their status becomes critical
  - ↳ **Adjust work flow** or tasks
  - ↳ **Evaluate** the project **team's ability** to **control quality** of software work products
- ▶ Many of the same metrics are used in both the process and project domain
- ▶ **Project metrics** are **used** for making **tactical (smart) decisions**
- ▶ They are **used** to adapt **project workflow** and **technical activities**
- ▶ Project metrics are used to
- ▶ **Minimize** the **development schedule** by making the **adjustments** necessary to avoid delays and **mitigate (to reduce)** potential (probable) problems and risks
- ▶ **Assess (evaluates) product quality** on an **ongoing basis** and guides to modify the technical approach to improve quality

# Product Metrics

- ▶ Product metrics **help software engineers** to gain **insight into** the **design and construction** of the **software** they build
  - ↳ By **focusing** on specific, **measurable attributes** of software engineering work products
- ▶ Product metrics **provide** a **basis** from which **analysis, design, coding and testing can be conducted** more **objectively** and **assessed** more **quantitatively**
  - ↳ Ex., Code Complexity Metric

# Types of Measures

## Categories of Software Measurement

### Direct measures of the

#### Software process

Ex., cost, effort, etc.

#### Software product

Ex., lines of code produced, execution speed, defects reported, etc.

### Indirect measures of the

#### Software product

Ex. functionality, quality, complexity, efficiency, reliability, etc.

## Software Measurement

### Metrics for Software Cost and Effort estimations

**Size Oriented** Metrics

**Function Oriented** Metrics

**Object Oriented** Metrics

**Use Case Oriented** Metrics

# Size-Oriented Metrics

- ▶ **Derived** by **normalizing** (standardizing) **quality** and/or **productivity** measures by **considering** the **size of the software** produced
- ▶ **Thousand lines of code (KLOC)** are often chosen as the normalization value

A set of simple size-oriented metrics can be developed for each project

Errors per KLOC (thousand lines of code)

Defects per KLOC

\$ per KLOC

Pages of documentation per KLOC

In addition, other interesting metrics can be computed, like

Errors per person-month

KLOC per person-month

\$ per page of documentation

- ▶ **Size-oriented** metrics **are not universally accepted** as the best way **to measure the software** process

Opponents argue that KLOC measurements

Are **dependent** on the programming **language**

**Penalize** well-designed but short programs

**Cannot** easily accommodate nonprocedural languages

**Require** a level of detail that may be difficult to achieve

# Function Oriented Metrics

- ▶ Function-oriented metrics use a measure of the **functionality delivered** by the application as a normalization value
- ▶ Most **widely used metric** of this type is the **Function Point**
  - ↳ **FP** = Count Total \* [0.65 + 0.01 \* Sum (Value Adjustment Factors)]
- ▶ Function Point **values on past projects** can be **used** to compute,
  - ↳ for example, the **average number of lines of code** per function point
- ▶ **Advantages**
  - ↳ FP is **programming language independent**
  - ↳ FP is based on **data** that are **more likely to be known in the early stages** of a project, making it more attractive as an estimation approach
- ▶ **Disadvantages**
  - ↳ FP **requires** some “**sleight of hand**” because the **computation** is based on **subjective data**
  - ↳ **Counts of the information** domain can be **difficult to collect**
  - ↳ FP has **no direct physical meaning**, it's just a number

# Object-Oriented Metrics

- ▶ **Conventional software project metrics** (LOC or FP) **can be used** to estimate object-oriented software projects
- ▶ However, these metrics **do not provide enough granularity** (detailing) for the schedule and effort adjustments that are required as you iterate through an evolutionary or incremental process
- ▶ Lorenz and Kidd suggest the following **set of metrics for OO projects**
  - Number of **scenario scripts**
  - Number of **key classes** (the highly independent components)
  - Number of **support classes**

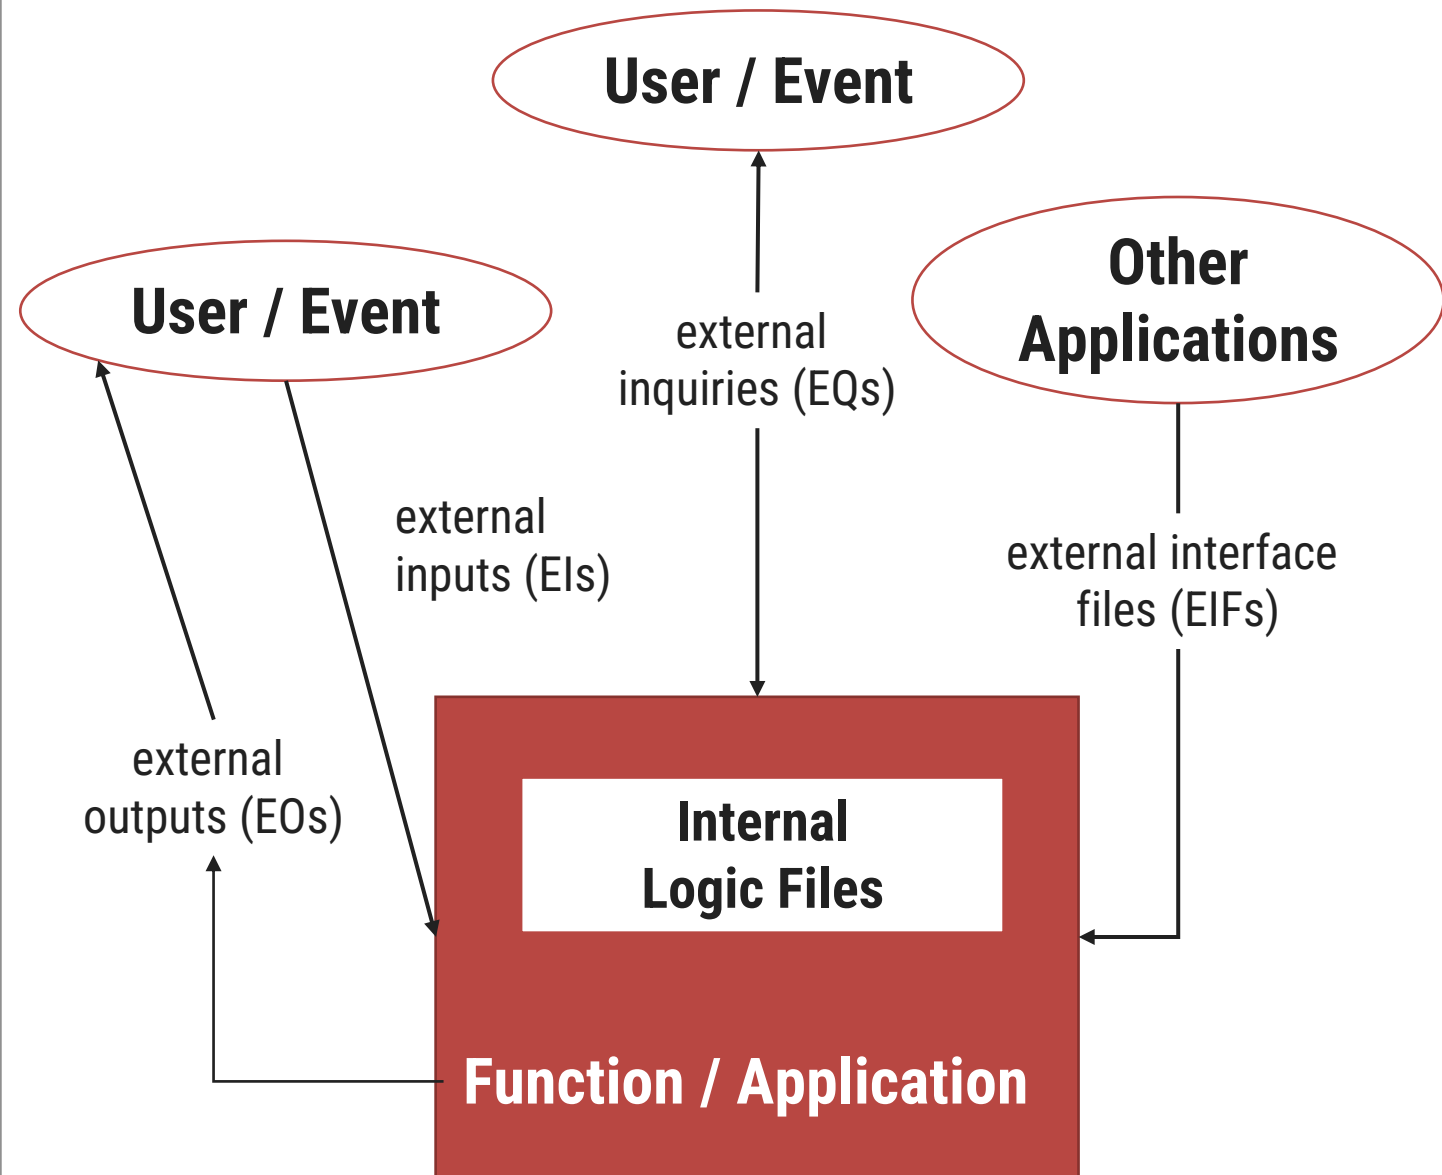

# Use Case Oriented Metrics

- ▶ Like FP, the **use case** is defined early in the software process, allowing it to be **used for estimation before significant** (valuable) **modeling and construction** activities are initiated
- ▶ **Use cases describe** (indirectly, at least) **user-visible functions** and **features** that are basic requirements for a system
- ▶ The **use case** is **independent of programming language**, because use cases can be created at vastly different levels of abstraction, there is **no standard “size” for a use case**
- ▶ **Without a standard measure** of what a use case is, its application as a normalization **measure is suspect** (doubtful).
  - Ex., effort expended / use case

# Function Point Metrics

- ▶ The **function point (FP)** metric can be **used** effectively as a **means for measuring the functionality** delivered by a system
- ▶ Using **historical data**, the **FP metric** can be **used** to
  - **Estimate the cost** or **effort** required to design, code, and test the software
  - **Predict the number of errors** that will be encountered during testing
  - **Forecast** the **number of components** and/or the **number of projected source lines** in the implemented system

# Function Point Components Cont.

Information domain values (components) are defined in the following manner

- ▶ **Number of external inputs (EIs)**

- ↪ input **data originates from a user** or is transmitted from another application

- ▶ **Number of external outputs (EOs)**

- ↪ external output is **derived data** within the application that **provides information to the user**
  - ↪ output refers to reports, screens, error messages, etc.

- ▶ **Number of external inquiries (EQs)**

- ↪ external inquiry is defined as an **online input that results in the generation of some immediate software response** in the form of an online output

- ▶ **Number of internal logical files (ILFs)**

- ↪ internal logical file is a **logical grouping of data** that **resides within** the application's **boundary** and is **maintained via** external **inputs**

- ▶ **Number of external interface files (EIFs)**

- ↪ external interface file is a **logical grouping of data** that **resides external** to the application **but provides information** that may be of use to the another application

# Function Point Calculation Example

Study of requirement specification for a project has produced following results

Need for **7 inputs**, **10 outputs**, **6 inquiries**, **17 files** and **4 external interfaces**

**Input** and **external interface** **function point** attributes are of **average complexity** and all **other function points** attributes are of **low complexity**

Determine **adjusted function points** assuming complexity **adjustment value is 32**.

Information Domain Value	Count		Weighting factor				
			Simple	Average	Complex		
External Inputs (EIs)	<b>7</b>	×	3	<b>4</b>	6	=	<b>28</b>
External Outputs (EOs)	<b>10</b>	×	<b>4</b>	5	7	=	<b>40</b>
External Inquiries (EQs)	<b>6</b>	×	<b>3</b>	4	6	=	<b>18</b>
Internal Logical Files (ILFs)	<b>17</b>	×	<b>7</b>	10	15	=	<b>119</b>
External Interface Files (EIFs)	<b>4</b>	×	5	<b>7</b>	10	=	<b>28</b>
Count total							<b>233</b>

Value adjustment factors **(VAF) = 32** given

$$\begin{aligned}\text{FP} &= \text{Count Total} * [ 0.65 + 0.01 * \Sigma(F_i) ] \\ &= \text{233} * [ 0.65 + 0.01 * \text{32} ] \\ &= \text{233} * 0.97 = \text{226.01}\end{aligned}$$

# Software Project Estimation

It can be **transformed** from a **black art** to a **series of systematic steps** that provide **estimates** with **acceptable risk**

To **achieve** reliable **cost** and **effort estimates**, a number of options arise:

- ▶ Delay estimation **until late in the project** (obviously, we can achieve 100 percent accurate estimates after the project is complete!)
- ▶ Base **estimates** on **similar projects** that have already been completed
- ▶ Use relatively simple **decomposition techniques** to generate project cost and effort estimates
- ▶ **Use** one or more **empirical models** for software cost and effort estimation.

# Software Project Decomposing

- ▶ Software **project estimation** is a form of **problem solving** and in most cases, the problem to be solved is **too complex to be considered in one piece**
- ▶ For this reason, **decomposing the problem**, re-characterizing it as a set of smaller problems is required
- ▶ Before an estimate can be made, the **project planner** must **understand the scope of the software** to be built and must generate an estimate of its “size”

## Decomposition Techniques

- |   |                                     |
|---|-------------------------------------|
| <b>1.</b> Software Sizing   | <b>3.</b> Process based Estimation  |
| <b>2.</b> Problem based Estimation<br>LOC (Lines of Code) based,<br>FP (Function Point) based | <b>4.</b> Estimation with Use-cases |

# Software Sizing

**Putnam and Myers suggest four different approaches to the sizing problem**

## ▶ “Fuzzy logic” sizing

- This approach uses **the approximate reasoning techniques** that are the cornerstone of fuzzy logic.

## ▶ Function Point sizing

- The planner develops **estimates of the information domain characteristics**

## ▶ Standard Component sizing

- Estimate the **number of occurrences** of each **standard component**
- Use **historical** project **data** to determine the **delivered LOC** size per standard component.

## ▶ Change sizing

- **Used** when **changes** are being **made** to **existing software**
- Estimate the **number** and **type of modifications** that must be accomplished
- An **effort ratio** is then **used** to **estimate** each **type of change** and the **size of the change**

# Problem Based Estimation

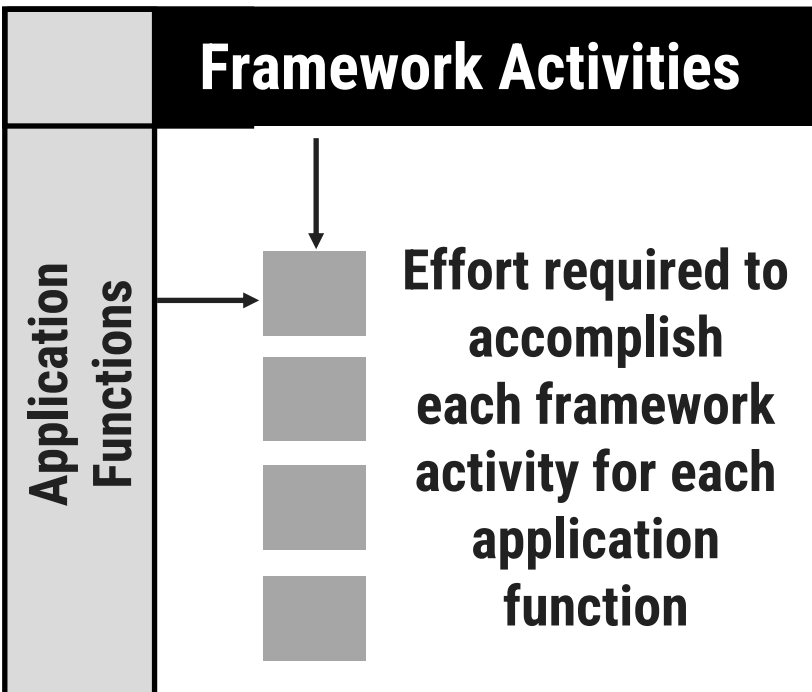

- ▶ **Start** with a **bounded** statement of **scope**
- ▶ **Decompose** the **software** into **problem functions** that can each be **estimated individually**
- ▶ **Compute** an **LOC** or **FP** value for **each function**
- ▶ **Derive cost** or **effort estimates** by applying the **LOC** or **FP** values to your **baseline productivity metrics**
  - ↪ Ex., LOC/person-month or FP/person-month
- ▶ **Combine function estimates** to produce an **overall estimate** for the **entire project**
- ▶ In general, the **LOC/pm** and **FP/pm** metrics should be computed by project domain
  - ↪ **Important factors** are **team size**, **application area** and **complexity**

# Process Based Estimation

Process-based estimation is obtained from “process framework”

- ▶ This is one of the **most commonly used technique**
- ▶ **Identify** the **set of functions** that the software needs to perform as obtained **from the project scope**
- ▶ **Identify** the **series of framework activities** that need to be performed for each function
- ▶ **Estimate the effort** (in **person months**) that will be **required to accomplish** each software process **activity** for **each function**
- ▶ **Apply average labor** rates (i.e., **cost/unit** effort) to the **effort estimated** for each process activity
- ▶ **Compute** the **total cost** and **effort** for each function and each framework activity.
- ▶ **Compare the resulting values** to those obtained by way of the **LOC and FP** estimates
- ▶ If **both** sets of **estimates agree**, then your numbers are **highly reliable**
- ▶ **Otherwise**, conduct **further investigation** and **analysis** concerning the **function** and **activity breakdown**

# Estimation with Use Cases

Developing an **estimation** approach **with** use cases is **problematic** for the following reasons:

- ▶ Use cases are **described using many different formats** and styles—there is no standard form.
- ▶ Use cases **represent an external view** (the user's view) of the software and can **therefore** be **written at many different levels** of **abstraction**
- ▶ Use cases **do not address** the **complexity of the functions** and features that are described
- ▶ Use cases **can describe complex behavior** (Ex., interactions) that **involve many functions** and features
- ▶ Although a number of investigators have considered use cases as an estimation input.

- ▶ **Before use cases** can be used for **estimation**,
  - ↳ the **level within the structural hierarchy** is established,
  - ↳ the **average length (in pages) of each use case** is determined,
  - ↳ the **type of software** (e.g., real-time, business, engineering/scientific, WebApp, embedded) is defined, and
  - ↳ a **rough architecture** for the system is **considered**
- ▶ Once these characteristics are established,
  - ↳ empirical data may be used to establish the estimated number of LOC or FP per use case (for each level of the hierarchy).
- ▶ Historical data are then used to compute the effort required to develop the system.

# Empirical Estimation Models

Source Lines of Code (SLOC)

Function Point (FP)

Constructive Cost Model  
(COCOMO)

## Source Lines of Code (SLOC)

- ▶ The **project size** helps to determine the resources, effort, and duration of the project.
- ▶ **SLOC** is **defined** as the **Source Lines of Code** that are **delivered as part of the product**
- ▶ The **effort spent on creating** the **SLOC** is **expressed** in relation to thousand lines of code (**KLOC**)
- ▶ This **technique includes** the **calculation of Lines of Code, Documentation of Pages, Inputs, Outputs, and Components** of a software program
- ▶ The SLOC technique is **language-dependent**
- ▶ The **effort required** to calculate **SLOC** may **not be the same** for all **languages**

# Software Development Project

Based on the development complexity

## Software Development Project Classification

**Organic**

**Application programs**

e.g. data processing programs

A **development project** can be considered of **organic** type, if the project deals with **developing a well understood application program**, the **size** of the **development team** is reasonably **small**, and the **team members** are **experienced** in **developing similar types of projects**

**Semidetached**

**Utility programs**

e.g. Compilers, linkers

A **development project** can be considered of **semidetached** type, if the **development consists** of a **mixture** of **experienced** & **inexperienced staff**. Team members may have **limited experience on related systems** but may be unfamiliar with some aspects of the system being developed.

**Embedded**

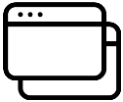

**System programs**

e.g. OS real-time systems

A **development project** is considered to be of **embedded** type, if the **software** being **developed** is **strongly coupled** to **complex hardware**, or if the **strict regulations** on the **operational procedures** exist

# Software Development Project Cont.

Model	Project Size	Nature of Project	Innovation	Dead Line	Development Environment
<b>Organic</b> 	Typically <b>2-50 KLOC</b>	<b>Small Size</b> Project, Experienced developers in the familiar environment, E.g. Payroll, Inventory projects etc.	Little	Not Tight	Familiar & In-house
<b>Semi Detached</b> 	Typically <b>50-300 KLOC</b>	<b>Medium Size</b> Project, Medium Size Team, Average Previous Experience, e.g. Utility Systems like Compilers, Database Systems, editors etc.	Medium	Medium	Medium
<b>Embedded</b> 	Typically <b>Over 300 KLOC</b>	<b>Large Project</b> , Real Time Systems, Complex interfaces, very little previous Experience. E.g. ATMs, Air Traffic Controls	Significant Required	Tight	Complex hardware & customer Interfaces

# COCOMO Model

## COCOMO (Constructive Cost Estimation Model)

was proposed by  
Boehm

According to Boehm,  
**software cost estimation**  
should be done through  
three stages:

Basic COCOMO

Intermediate COCOMO

Complete COCOMO

# Basic COCOMO Model

The **basic COCOMO** model gives an **approximate estimate** of the project parameters

The **basic COCOMO estimation** model is given by the **following expressions**

$$Effort = a_1 + (KLOC)^{a_2} PM$$

$$Tdev = b_1 \times (Effort)^{b_2} Months$$

- **KLOC** is the estimated size of the software product expressed in Kilo Lines of Code
- **a<sub>1</sub>, a<sub>2</sub>, b<sub>1</sub>, b<sub>2</sub>** are constants for each category of software products,
- **Tdev** is the estimated **time to develop** the software, **expressed in months**,
- **Effort** is the **total effort required to develop** the software **product**, expressed in **person months (PMs)**.

Project	a <sub>1</sub>	a <sub>2</sub>	b <sub>1</sub>	b <sub>2</sub>
Organic	2.4	1.05	2.5	0.38
Semidetached	3.0	1.12	2.5	0.35
Embedded	3.6	1.20	2.5	0.32

# Basic COCOMO Model Cont.

- ▶ The effort estimation is expressed in **units of person-months (PM)**
- ▶ It is the **area under the person-month plot** (as shown in fig.)
- ▶ An **effort of 100 PM**
  - ➔ **does not** imply that **100 persons** should **work for 1 month**
  - ➔ **does not** imply that **1 person** should be **employed for 100 months**
  - ➔ **it denotes** the **area under** the **person-month curve** (fig.)
- ▶ **Every line of source** text should be **calculated** as **one LOC** irrespective of the **actual number of instructions** on that line
- ▶ If a **single instruction spans several lines** (say **n lines**), it is **considered** to be **nLOC**
- ▶ The values of  **$a_1$ ,  $a_2$ ,  $b_1$ ,  $b_2$**  for different categories of products (i.e. organic, semidetached, and embedded) as given by Boehm
- ▶ He derived the expressions by examining historical data collected from a large number of actual projects

Fig. Person Month Curve

# Basic COCOMO Model Cont.

- ▶ **Insight** into the **basic COCOMO** model can be obtained by **plotting the estimated characteristics** for different software sizes
- ▶ **Fig.1** shows a **plot of estimated effort** versus **product size**
- ▶ From fig. we can observe that the **effort** is somewhat **superlinear** in the **size of the software** product
- ▶ The **effort** required to develop a product **increases** very **rapidly with project size**
- ▶ The **development time versus the product size** in KLOC is plotted in fig. 2
- ▶ From fig., it can be observed that the **development time** is a **sublinear** function of **the size** of the product
- ▶ i.e. when the **size of the product** increases by **two times**, the time to develop the **product does not double** but **risers moderately**
- ▶ From fig., it can be observed that the development time is roughly the same for all the three categories of products

Fig. 1

Fig. 2

# Basic COCOMO Model Cont.

- ▶ **Effort** and the **duration estimations** obtained **using** the **COCOMO** model are called as **nominal effort** estimate and nominal **duration estimate**
- ▶ The term **nominal implies** that
  - ➔ if anyone **tries to complete the project** in a **time shorter** than the **estimated** duration, then the **cost will increase drastically**
  - ➔ But, if anyone **completes the project over a longer period** of time than the **estimated**, then there is almost **no decrease** in the **estimated cost value**

**Example:** Assume that the **size** of an **organic type** software product **has been estimated** to be **32,000 lines of source code**. Assume that the **average salary** of software **engineers** be **Rs. 15,000/- per month**. **Determine** the **effort required** to develop the software product **and** the **nominal development time**

$$\text{Effort} = a_1 + (KLOC)^{a_2} PM$$

$$= 2.4 + (32)^{1.05} PM$$

$$= 41 PM$$

$$Tdev = b_1 \times (Effort)^{b_2} Months$$

$$= 2.5 \times (41)^{0.38} Months$$

$$= 10 Months$$

**Cost** required to develop the product = 10 x 15000 = Rs. **1,50,000/-**

# Intermediate COCOMO model

- ▶ The **basic COCOMO** model **assumes** that **effort** and **development time** **are functions** of the **product size alone**
- ▶ However, a **host of other** project **parameters** besides the product size **affect** the **effort required** to develop the product as well as the **development time**
- ▶ Therefore, **in order to obtain an accurate estimation** of the effort and project **duration**, the **effect** of all relevant **parameters** must be **taken** into **account**
- ▶ The **intermediate COCOMO** model **recognizes this fact** and refines the initial estimate obtained using the basic COCOMO expressions **by using a set of 15 cost drivers (multipliers)** based on **various attributes** of software development
  - ➔ For example, if modern programming practices are used, the initial estimates are scaled downward by multiplication with a cost driver having a value less than 1
- ▶ It **requires** the project manager **to rate** these **15** different **parameters** for a particular **project** on a **scale of one to three**.
- ▶ Then, **depending** on these **ratings**, **appropriate cost driver values** which should be **multiplied with the initial estimate** obtained using the basic COCOMO.

# Intermediate COCOMO model Cont.

**The cost drivers** can be **classified** as being attributes **of the following items**

- ▶ **Product:** The characteristics of the product that are considered include the **inherent complexity** of the product, **reliability requirements** of the product, etc.
- ▶ **Computer:** Characteristics of the computer that are considered include the **execution speed** required, **storage space** required etc.
- ▶ **Personnel:** The attributes of development personnel that are considered include the **experience level of personnel**, **programming capability**, **analysis capability**, etc.
- ▶ **Development Environment:** Development environment attributes capture the **development facilities available** to the developers. An important parameter that is considered is the **sophistication of the automation (CASE) tools used** for software development

# Complete COCOMO model

- ▶ A major **shortcoming** of both the **basic** and **intermediate COCOMO** models is that they **consider** a software product **as a single homogeneous entity**
- ▶ Most **large systems** are **made** up several **smaller sub-systems**
- ▶ These **sub-systems** may have widely **different characteristics**
  - E.g., **some sub-systems** may be considered as **organic type**, some **semidetached**, and some **embedded**
  - Also for **some subsystems** the **reliability requirements** may be **high**, for some the **development team** might **have no previous experience** of similar development etc.
- ▶ The **complete COCOMO** model **considers** these differences in **characteristics** of the **subsystems** and **estimates** the effort and development time **as the sum of the estimates for the individual subsystems**
- ▶ The **cost** of each **subsystem** is **estimated separately**
- ▶ This approach **reduces** the **margin of error** in the final **estimate**

# Project Scheduling & Tracking

It is an **action** that **distributes** estimated **effort across** the **planned** project **duration**, by **allocating** the effort **to specific software engineering tasks**

## Scheduling Principles

Compartmentalization

Interdependency

Time Allocation

Define Responsibilities

Define Outcomes

Define Milestones

Effort Validation

# Scheduling Principles

## ▶ Compartmentalization

- The **product** and **process** must be **decomposed** into a **manageable number** of **activities** and **tasks**

## ▶ Interdependency

- **Tasks** that can be completed in **parallel** must be **separated** from those that must be completed **serially**

## ▶ Time Allocation

- Every task has **start** and **completion** dates that **take** the **task interdependencies** into account

## ▶ Effort Validation

- Project manager must **ensure** that on any **given day** there are **enough staff** members assigned to **complete the tasks** within the **time estimated** in the project plan

## ▶ Define Responsibilities

- **Every** scheduled **task** needs to be **assigned to** a **specific** team **member**

## ▶ Define Outcomes

- **Every task** in the schedule **needs** to **have** a **defined outcome** (usually a work product or deliverable)

## ▶ Defined Milestones

- A **milestone** is **accomplished** when one or more **work products** from an engg task have **passed quality review**

# Effort Distribution

- ▶ General guideline: **40-20-40 rule**
  - ↳ **40%** or more of all effort allocated to **analysis and design tasks**
  - ↳ **20%** of effort allocated to **programming**
  - ↳ **40%** of effort allocated to **testing**
- ▶ **Characteristics** of each **project** dictate the **distribution of effort**
- ▶ Although most software organizations encounter the following **projects types**:
  - ↳ **Concept Development**
    - initiated to explore **new business concept** or new application of technology
  - ↳ **New Application Development**
    - **new product** requested by customer
  - ↳ **Application Enhancement**
    - major **modifications to function**, performance or interfaces (observable to user)
  - ↳ **Application Maintenance**
    - **correcting**, adapting or **extending** existing **software** (not immediately obvious to user).
  - ↳ **Reengineering**
    - **rebuilding** all (or part) of a **existing** (legacy) **system**

# Scheduling methods

- ▶ Two project scheduling methods that can be applied to software development.
  - ↳ Program Evaluation and Review Technique (**PERT**)
  - ↳ Critical Path Method (**CPM**)
- ▶ Both techniques are **driven** by **information already** developed in **earlier project planning** activities:
  - ↳ estimates of effort
  - ↳ a decomposition of the product function
  - ↳ the selection of the appropriate process model and task set
  - ↳ decomposition of the tasks that are selected
- ▶ Both **PERT** and **CPM** provide **quantitative tools** that allow you to:
  - ↳ **Determine the critical path**—the chain of tasks that determines the duration of the project
  - ↳ **Establish “most likely” time estimates** for individual tasks by applying statistical models
  - ↳ **Calculate “boundary times”** that define a “time window” for a particular task

# Project Schedule Tracking

- ▶ The project schedule provides a road map for a software project manager.
- ▶ It defines the tasks and milestones.
- ▶ Several ways to track a project schedule:
  - ➔ Conducting **periodic project** status **meeting**
  - ➔ **Evaluating** the **review results** in the software process
  - ➔ **Determine** if formal **project milestones** have been **accomplished**
  - ➔ **Compare** actual start date to planned start date for each task
  - ➔ Informal **meeting with practitioners**

  - ➔ Project Staffing, Project Problems, Project Resources, Reviews, Project Budget

## Gantt chart

A **Gantt chart**, commonly used in **project management**, is one of the most **popular** and **useful ways** of **showing activities (tasks or events)** displayed **against time**.

On the **left of the chart** is a **list of the activities** and along the **top** is a suitable **time scale**.

Each **activity** is **represented** by a **bar**; the **position** and **length** of the bar reflects the **start date**, **duration** and **end date** of the activity. This allows you to see at a glance:

# Gantt chart Cont.

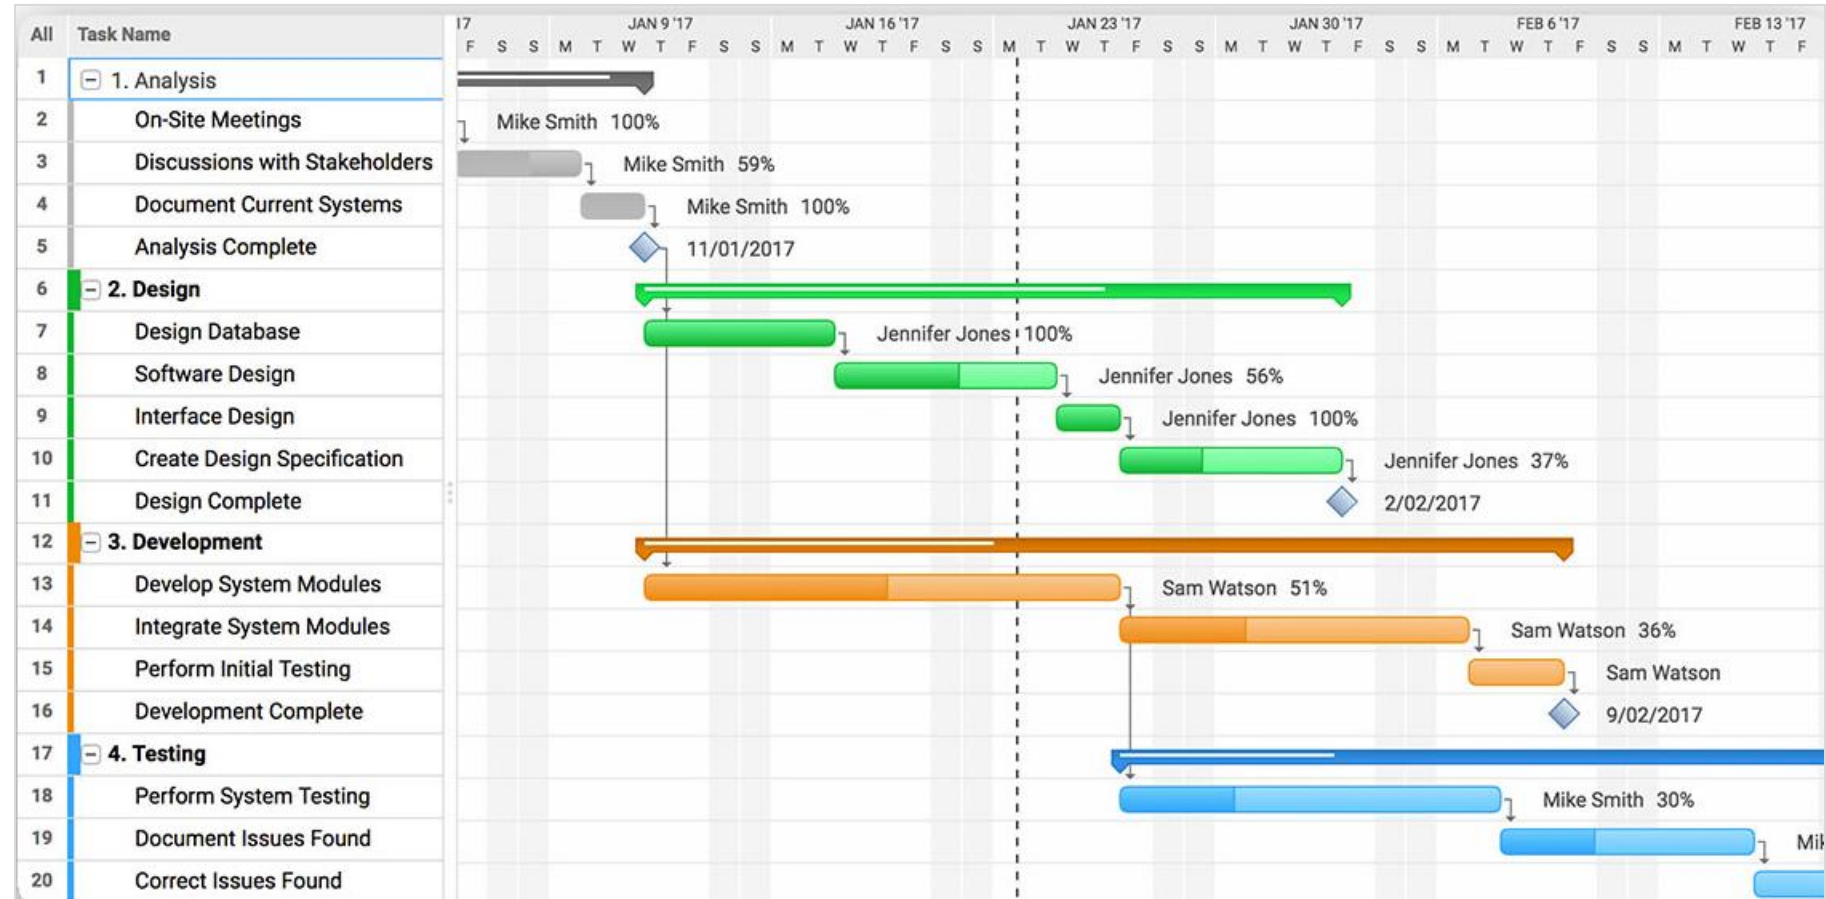

What the various activities are

When each activity begins and ends

How long each activity is scheduled to last

Where activities overlap with other activities, and by how much

The start and end date of the whole project

A **risk** is a **potential (probable) problem** – which might **happen and might not**

### Conceptual definition of risk

- ▶ Risk **concerns future happenings**
- ▶ Risk **involves change** in mind, **opinion, actions, places**, etc.
- ▶ Risk **involves** choice and the **uncertainty** that choice entails

### Two characteristics of risk

**Uncertainty**

The risk **may** or **may not happen**, so there are no 100% risks (some of those may called constraints)

**Loss**

If the **risk** becomes a **reality** and **unwanted consequences** or **losses** occur

# Risk Categorization: Approach-1

## ► Project risks

- They **threaten** the **project plan**
- If they become real, it is likely that the **project schedule will slip** and that **costs will increase**

## ► Technical risks

- They **threaten the quality** and **timeliness** of the software to be produced
- If they become real, **implementation may become difficult** or impossible

## ► Business risks

- They **threaten** the **feasibility** of the **software** to be built
- If they become real, they **threaten the project** or the **product**

## Sub-categories of Business risks

### ► Market risk

- Building an **excellent product** or system that **no one really wants**

### ► Strategic risk

- Building a **product that no longer fits into** the overall **business strategy** for the company

### ► Sales risk

- Building a **product** that the **sales force doesn't understand** how to **sell**

### ► Management risk

- **Losing** the **support** of **senior management** due to a change in focus or a change in people

### ► Budget risk

- **Losing budgetary** or **personnel commitment**

# Risk Categorization: Approach-2

## ► Known risks

- Those **risks** that can be **uncovered after careful evaluation** of
  - the **project plan**, the **business and technical environment** in which the project is being developed, and other **reliable information sources** (Ex. unrealistic delivery date)

## ► Predictable risks

- Those **risks** that are **deduced** (draw conclusion) from **past project** experience (Ex. past turnover)

## ► Unpredictable risks

- Those **risks** that can and do **occur**, but are **extremely difficult** to **identify** in **advance**

### Risk Strategies (Reactive vs. Proactive)

#### Reactive risk strategies

- "**Don't worry, I will think of something**".
- The **majority of software teams** and managers **rely** on this **approach**
- **Nothing** is **done** about **risks until something** goes **wrong**
- The **team** then **flies into action** in an attempt to **correct the problem rapidly** (fire fighting)
- **Crisis management** is the **choice** of management **techniques**

#### Proactive risk strategies

- **Steps** for **risk management** are **followed**
- Primary **objective** is to **avoid risk** and to have an **emergency plan in place** to **handle** unavoidable **risks** in a **controlled and effective manner**

# Steps for Risk Management

1. **Identify** possible **risks** and recognize what can go wrong
2. **Analyze** each **risk** to estimate the probability that it will occur and the impact (i.e., damage) that it will do if it does occur
3. **Rank** the **risks** by probability and impact. Impact may be negligible, marginal, critical, and catastrophic.
4. **Develop** a contingency **plan** to **manage** those **risks** having high probability and high impact

# Risk Identification

- ▶ Risk identification is a **systematic attempt** to **specify threats** to the project **plan**
- ▶ By **identifying** known and predictable **risks**, the project manager **takes a first step** toward,
  - **avoiding them** when **possible**
  - **controlling them** when necessary
- ▶ **Generic Risks**
  - **Risks** that are a potential **threat** to **every** software **project**
- ▶ **Product-specific Risks**
  - Risks that can be **identified only by clear understanding** of the **technology**, the **people** and the **environment**, that is **specific to the software** that is to be built

# Known and Predictable Risk Categories

- ▶ One method for identifying risks is **to create a risk item checklist**
- ▶ The checklist can be used for risk identification which **focuses on some subset of known and predictable risks** in the following generic subcategories:
  - **Product Size:** risks **associated with overall size** of the software to be built
  - **Business Impact:** risks **associated with constraints** imposed by **management** or the **marketplace**
  - **Customer Characteristics:** risks associated with **sophistication of the customer** and the **developer's ability to communicate with the customer** in a timely manner
  - **Process Definition:** risks associated with the **degree to which the software process has been defined** and is followed
  - **Development Environment:** risks associated with **availability and quality of the tools** to be used to build the project
  - **Technology to be Built:** risks associated with **complexity of the system to be built** and the “**newness**” of the **technology** in the system
  - **Staff Size and Experience:** risks associated with **overall technical and project experience** of the software **engineers** who will do the work

# Risk Estimation (Projection)

- ▶ **Risk** projection (or **estimation**) **attempts to rate each risk in two ways**
  - ↳ The **probability** that the **risk is real**
  - ↳ The consequence (**effect**) of the **problems** associated with the risk
- ▶ **Risk Projection/Estimation Steps**
  - ↳ **Establish a scale** that reflects the **perceived** likelihood (**probability**) of a **risk**. *Ex., 1-low, 10-high*
  - ↳ Explain the **consequences of the risk**
  - ↳ **Estimate** the **impact of the risk** on the project and product.
  - ↳ **Note** the **overall accuracy of the risk projection** so that there will be **no misunderstandings**

- ▶ Risk Mitigation, Monitoring, and Management (RMMM)
- ▶ An **effective strategy for dealing with risk** must consider three issues
  - Risk **mitigation** (i.e., **avoidance**)
  - Risk **monitoring**
  - Risk **management** and **contingency planning**

## RMMM

---

**Risk Mitigation** is a **problem avoidance activity**

**Risk Monitoring** is **a project tracking activity**

**Risk Management** includes **contingency plans** that risk will occur

# Risk Mitigation

- ▶ Risk **mitigation (avoidance)** is the **primary strategy** and is **achieved through a plan**
- ▶ **For Ex., Risk of high staff turnover**
- ▶ To mitigate this risk, you would develop a strategy for reducing turnover.
- ▶ The possible steps to be taken are:
  - **Meet with current staff** to determine **causes for turnover** (e.g., poor working conditions, low pay, and competitive job market)
  - **Mitigate** those **causes** that are **under your control** before the project starts
  - Once the **project commences**, assume **turnover will occur** and develop **techniques** to **ensure continuity** when **people leave**
  - **Organize project teams** so that **information** about **each development** activity is **widely dispersed**
  - **Define** work **product standards** and establish mechanisms to **be sure** that all **models** and **documents** are **developed** in a **timely manner**
  - Conduct **peer reviews of all work** (so that more than one person is “up to speed”).
  - Assign **a backup staff member** for every **critical technologist**

# RMMM PLAN

- ▶ The RMMM **PLAN documents** all work performed as part of **risk analysis** and used by the project manager as part of the **overall project plan**
- ▶ Some software teams do not develop a formal RMMM document, rather each risk is documented individually using a **Risk information sheet (RIS)**
- ▶ In most cases, RIS is maintained using a database system.
- ▶ So Creation and information entry, priority ordering, searches and other analysis may be accomplished easily.
- ▶ The format of RIS is describe in diagram

## Risk information sheet (RIS)

Risk information sheet			
Risk ID: P02-4-32	Date: 5/9/02	Prob: 80%	Impact: high
<b>Description:</b> Only 70 percent of the software components scheduled for reuse will, in fact, be integrated into the application. The remaining functionality will have to be custom developed.			
<b>Refinement/context:</b> Subcondition 1: Certain reusable components were developed by a third party with no knowledge of internal design standards. Subcondition 2: The design standard for component interfaces has not been solidified and may not conform to certain existing reusable components. Subcondition 3: Certain reusable components have been implemented in a language that is not supported on the target environment.			
<b>Mitigation/monitoring:</b> 1. Contact third party to determine conformance with design standards. 2. Press for interface standards completion; consider component structure when deciding on interface protocol. 3. Check to determine number of components in subcondition 3 category; check to determine if language support can be acquired.			
<b>Management/contingency plan/trigger:</b> RE computed to be \$20,200. Allocate this amount within project contingency cost. Develop revised schedule assuming that 18 additional components will have to be custom built; allocate staff accordingly. Trigger: Mitigation steps unproductive as of 7/1/02			
<b>Current status:</b> 5/12/02: Mitigation steps initiated.			
Originator: D. Gagne		Assigned: B. Laster
